Abstract

The risk of a terrorist attack in the U.S. has created challenges on how to effectively treat toxicities that result from exposure to chemical weapons. To address this concern, the U.S. has organized a trans-agency initiative across academia, government, and industry to develop and approve drugs to treat novel injury resulting from exposure to chemical threat agents. We sought to develop and evaluate an interactive educational session that provides hands-on instruction on how to re-purpose FDA approved drugs as therapeutics in treating toxicity from exposure to chemical weapons. Due to the COVID-19 pandemic, the Rutgers Summer Undergraduate Research Fellowship was run remotely for 6-weeks. In addition to independent virtual projects, students met twice weekly with instruction to participate in career development activities. Twenty undergraduate students participated in a four-hour session that included: 1) overview of the CounterACT program from the NIH Program Officer, 2) original research in novel methodologies to evaluate drug efficacy from a toxicology PhD student, and 3) an interactive session where teams of students were provided lists of FDA approved drugs to evaluate potential mechanisms of action and suitability as countermeasures for 4 chemical weapon case scenarios. The interactive session culminated in a competition for the best grant sales pitch. Pre- and postprogram self-assessments using 5-point Likert rating scales were conducted online. Each participant had a unique identifier that was blinded to instructors and used to evaluate understanding of key programmatic objectives of the activity. From this interactive training, students improved their understanding of 1) the ability of chemical weapons to cause long-term toxicities (means pre:1.5, post:3.4; p=0.001); 2) how to apply the mechanism of action for a drug to a new clinical indication (means pre:1.4, post:3.6; p=0.001); and 3) re-purposing FDA-approved drugs to treat exposure to chemical weapons (means pre:0.8, post:2.5; p=0.001). Taken together, use of an interactive training exercise can provide students new insights into drug development for chemical weapon toxicities.

Interactive Training Overview

Part 1: Each team was assigned a case study scenario which included the chemical weapon exposure scenario, known pathological changes, clinical symptoms and mechanisms of toxicity.
   - Breakout room 1: Identify 5 properties desired in a therapy to treat the toxicity associated with the chemical weapon in the case study.
   - Breakout room 2: After hearing properties from other teams, points were assigned to each property according to its importance in treating chemical weapon toxicity.

Part 2: Moderator presents an example rubric to evaluate the utility of potential therapies researched during the pre-work.
   - Breakout room 1: Teams apply their rubric to three of the FDA-approved drugs from the pre-work in order to identify the most promising intervention.
   - Breakout room 2: Prepare a 3-minute grant sales pitch that highlights the promise of their top candidate drug for re-purposing to treat chemical weapon toxicity.

Part 3: In the main Zoom room, each team presented their therapeutic intervention and the audience including other participants, SURF leadership, and invited speakers voted on the best ‘sales pitch’. Gift cards were provided to the top 3.

4 Chemical Weapon Case Scenarios

- Phosgene Oxime Dermal Toxicity
- Tetramethylenedisulfotetramine Neurotoxicity
- Parathion Neurotoxicity
- Chlorine Pulmonary Toxicity
- Pesticide Toxicology

Main Takeaway

An interactive training exercise can provide undergraduate students new insights into drug development for chemical weapon toxicities.
